

The Effect of Mindfulness Meditation and Napping on Procedural Memory Consolidation in Humans

PSYC 211 Data Blitz

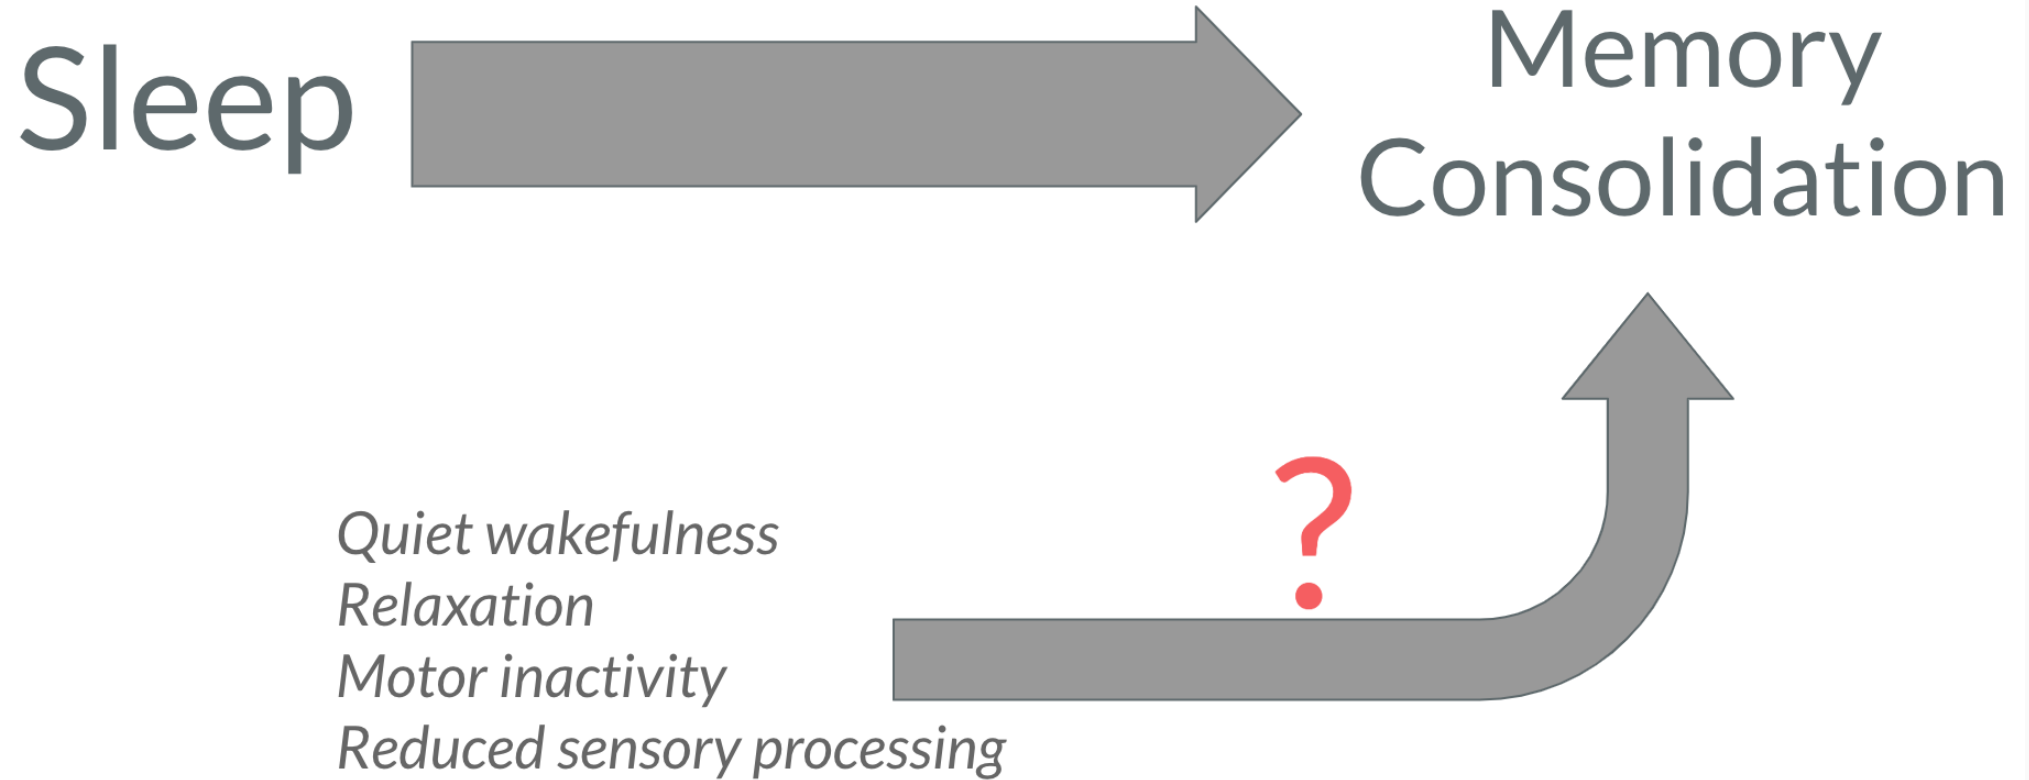

Mohammad Dastgheib

23 November 2021

A Very Brief Background

- Sleep
 - non-REM and REM
 - non-REM: Stage 1, 2, SWS (deep sleep)
- Procedural memory
 - stimulus-response learning, acquisition of motor skills, etc.
- Memory Consolidation
 - transforming information encoded during into a stable network of representation in the long-term memory
 - memories are "replayed"
 - sleep is great because the brain does not process incoming sensory information

Is memory consolidation exclusive to sleep?

Is memory consolidation exclusive to sleep?

Hypothesis: Participants in the NAP and MED conditions will outperform WAKE condition

The Experiment

Day-1

Day-2

Initial Interview

Learning Phase

Experiment

Test Phase

Familiarize the participants with the environment

Marble Maze task
(100 trials)

NAP, MED, WAKE
(60 minutes)

Marble Maze task
(50 trails)
Debriefing

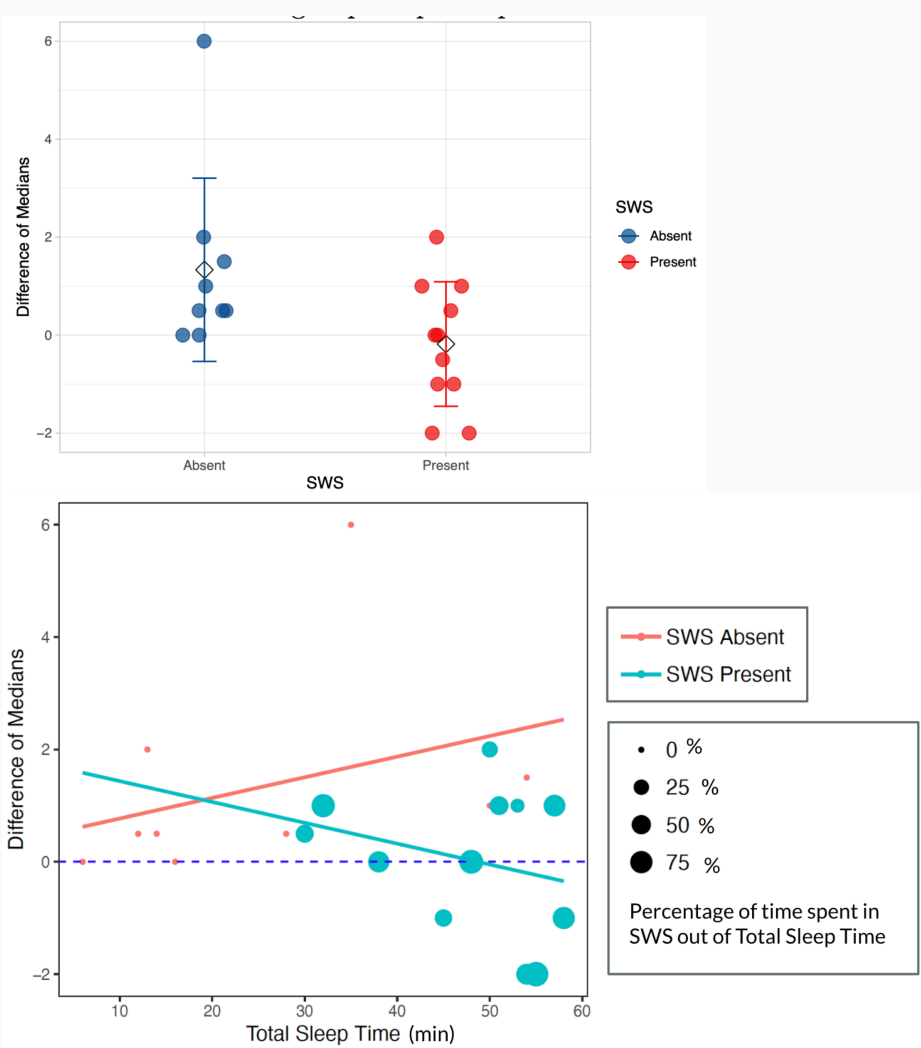

DependentVariable = [median of trials 1 – 10 of test phase] and [median of trials trials 91 – 100 of learning phase]

Results

Results

Results

- Mixed-design to ANOVA
 - 4 (condition) x 2 (time)
 - significant main effect of Time
 - no significant main effect of Condition
 - no significant Interaction

Results & Discussion

- Mixed-design to ANOVA
 - 4 (condition) x 2 (time)
 - significant main effect of Time
 - no significant main effect of Condition
 - no significant Interaction
- diving the number of NAP condition into two group decreased the sample size (?)
- *sleep inertia*

the LC project*

LC Project

- Part One: Aims
- Part Two: Overall procedure

Aims

1. Characterize relationships between LC and perceptual processing
2. Characterize relationships between LC and visual memory
3. Determine whether relationships with LC are shared between perception and memory

Aims

1. **Characterize relationships between LC and perceptual processing**
 - **poorer LC integrity is associated with:**
 - **poorer performance on *auditory* and *visual perceptual* tasks**
 - **less modulation of perceptual performance by a stressor**
2. Characterize relationships between LC and visual memory
3. Determine whether relationships with LC are shared between perception and memory

Aims

1. Characterize relationships between LC and perceptual processing
2. **Characterize relationships between LC and visual memory**
 - **poorer LC integrity is associated with:**
 - **poorer performance on *change detection* and *mnemonic similarity* tasks**
 - **less modulation of perceptual performance by a stressor**
3. Determine whether relationships with LC are shared between perception and memory

Aims

1. Characterize relationships between LC and perceptual processing
2. Characterize relationships between LC and visual memory
3. **Determine whether relationships with LC are shared between perception and memory**
 - **by how much LC integrity similarly or differentially gives rise to variations in perceptual and memory performance**

Overall Components

- Neuroimaging
 - Task fMRI, Neuromelanin imaging, Structural scan, Hi.Res. tractography, Functional connectivity
- Handgrip stress manipulation
 - different levels to manipulate LC activity
- Perceptual tasks
 - Auditory, Visual
- Visual memory tasks
 - Mnemonic similarity task (MST), Change detection task
- Metacognition

Neuroimaging

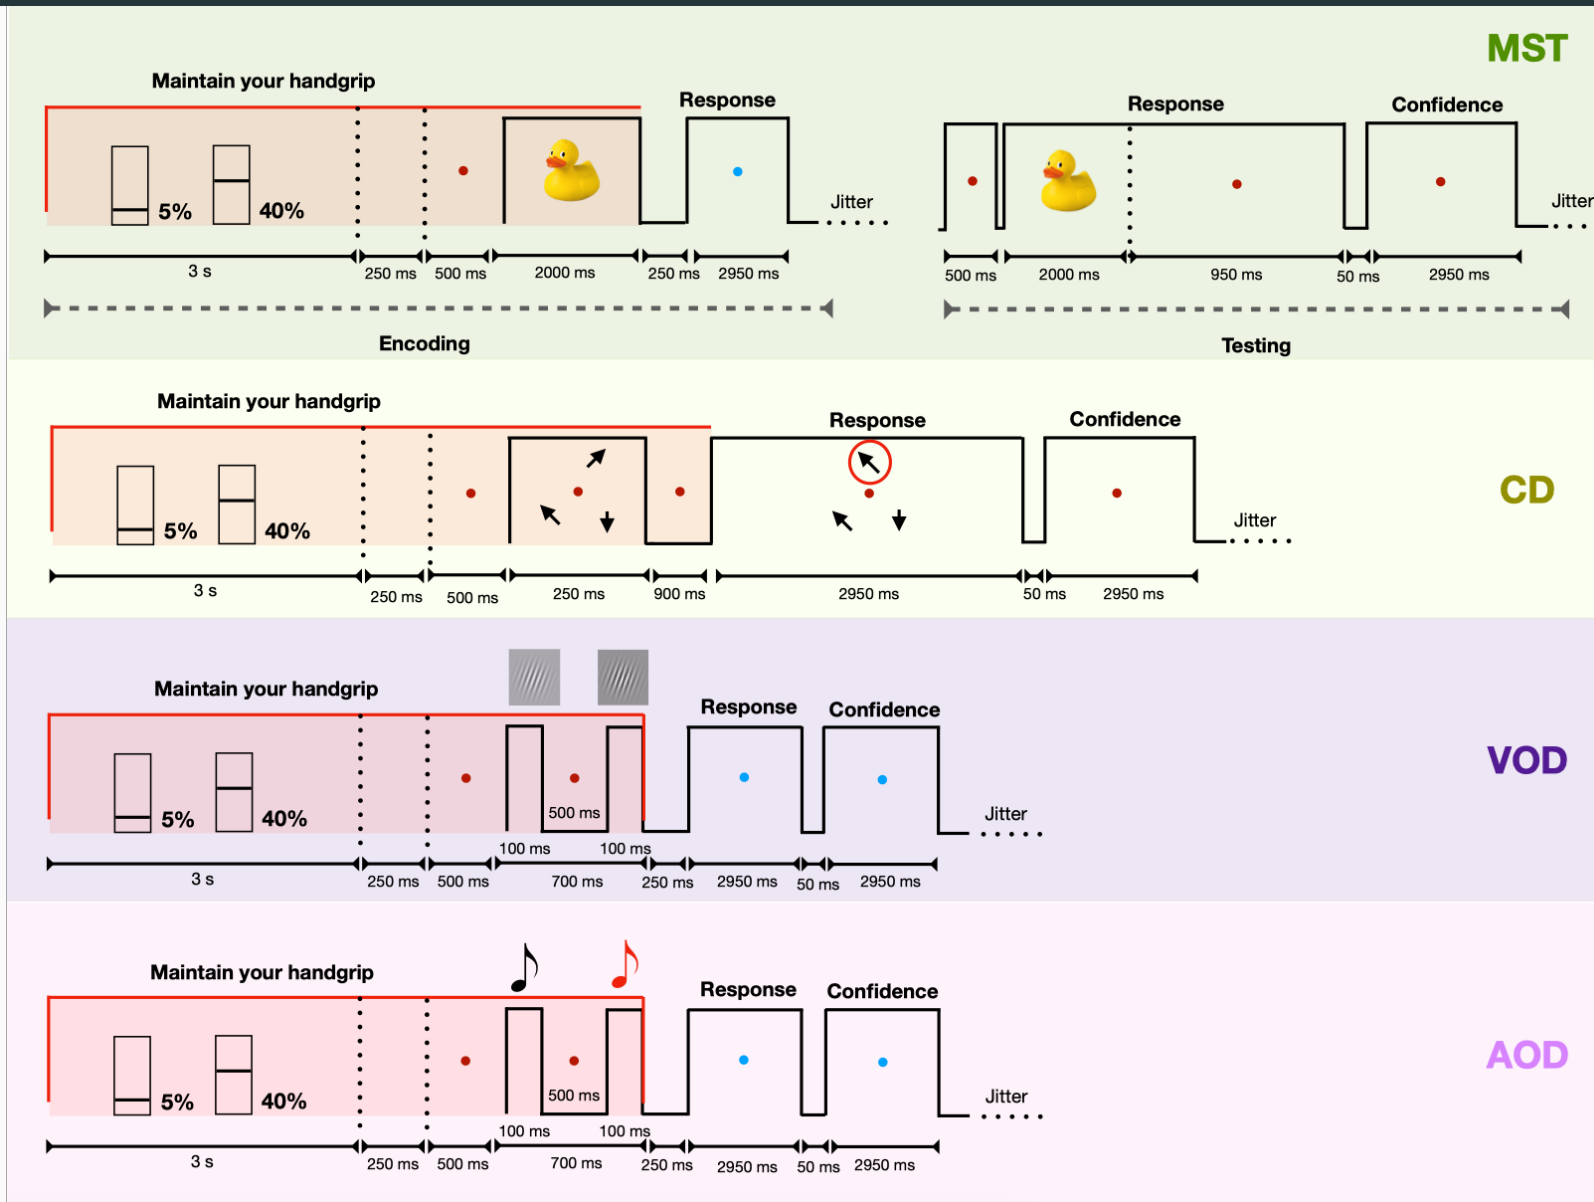

- *in vivo* assessments of LC integrity in humans
 - Very difficult — small size and deeply located in the brainstem

Neuromelanin

- dark and insoluble pigment
- by-product of catecholamine synthesis
- accumulates across the lifespan (~late middle age)
- chelates (attaching a ligand to metals) such as copper and iron
 - results in paramagnetic, T1-shortening effects

Neuromelanin acts as a natural contrast agent for non-invasive, *in vivo* assessment of LC integrity via MRI

All behavioural tasks
